For example, if the charge held in the capacitor at some time is (Q) , then the symbol $(\dot{Q}, \text{ or } dQ/dt)$ means the rate of increase of (Q) with respect to time. If the capacitor is discharging, (\dot{Q}) is negative. Expressed otherwise, the symbol to be used for the rate at which a capacitor is losing charge is $(-\dot{Q})$.

Consider a metal plate P 1 having area A with some positive charge +Q be given to the plate. Let its potential be V. Its capacity is given by, $C = \frac{Q}{V}$; Now consider another insulated metal plate P 2 held near plate P 1 induction, a negative charge is produced on the nearer face and an equal positive charge develops on the farther face of P 2 as shown in figure (a) below.

In Part 1 of this series [1], a brief history of switched-capacitor voltage multiplier was reviewed starting with Greinacher's voltage doubler in 1914 [2]. A capacitor is a simple device. It is basically just two conductors sandwiched with an insulator between them. Engineers know the basic laws of physics: capacitance (the amount of charge) increases directly with the area of the conductors (plates), inversely with their distance apart, and directly with the dielectric constant of the insulation. Given a moment to ...
