Factors That Affect Specific Energy. Several factors can affect the specific energy of a lithium-ion battery, which is an important metric for measuring the power and performance of your battery. One key factor is temperature. Lithium-ion batteries operate best at room temperature, with their specific energy decreasing as temperatures rise or fall.

By carefully considering these factors and selecting a battery that aligns with the specific requirements of the application, developers can ensure a reliable and long-lasting power supply for the IoT devices. Battery life is determined by the match between battery and device behavior. Battery Type: Electrochemistry, capacity, and energy density

The battery cycle life for a rechargeable battery is defined as the number of charge/recharge cycles a secondary battery can perform before its capacity falls to 80% of what it originally was. This is typically between 500 and 1200 cycles. The battery shelf life is the time a battery can be stored inactive before its capacity falls to 80%.

When figuring out how long your battery will last in watt-hours, you need to know the capacity of your battery in watt-hours and how much power you're using. The capacity of a AA battery is usually about 2200 mAh or 8.4 watt-hours. A laptop might use 20 watts, so a AA battery could power it for $8.4/20=0.42$ hours or about 25 minutes.

When looking at the Wikipedia page for Lithium-ion batteries, one can see that there are some technical details such as Specific Energy and Specific Power, but I don't know how to connect them.. For example, one can see this: Specific Energy: 100-265 Wh/kg. and. Specific Power: 250 - 340 W/kg. According to the theory, power equals energy divided by time; i.e. $1 \text{ W} = 1 \text{ Wh/t}$.
