The ceramic separator also enables our battery design to use a customized catholyte material, better suited for the voltage and transport requirements of the cathode. The requirements for the ceramic separator are different from that of the catholyte. The former requires dendrite resistance and stability to lithium-metal.

Advantages of Hybrid Ceramic-Polymer Materials. Stern describes traditional ceramic electrolytes as similar to hard candy - think M& Ms - poured into the space between the battery anode and cathode. The hard ceramics provide safety and energy storage advantages, but are limited in how much they contact the electrodes to transfer ionic charges.

Lithium-ion batteries (LIBs) and ceramic fuel cells (CFCs) are important for energy storage and conversion technologies and their materials are central to developing advanced applications.

Inorganic materials mainly include ceramics (boehmite-AlOOH, alumina-Al2O3), while organic materials mainly include PVDF, aramid, and others. Alumina coating, Boehmite coating, and PVDF (Polyvinylidene fluoride) coating are three commonly used methods for enhancing the performance and functionality of battery separators.

Today, the company is on track to produce a prototype solid-state battery made without graphite. Instead of graphite, ION uses a ceramic cell design that requires no anode material. Its cell extracts the lithium already present in cathode materials and uses its highly conductive ceramic to plate it as lithium metal into engineered voids.
