However, compensation components have to be chosen carefully. A compensation scheme can indeed improve stability, but can also lead the system to instability, depending on the choice of component values. Series compensation is the method of improving the system voltage by connecting a capacitor in series with the transmission line. With these the size of the compensation capacitor is chosen by the design engineer to suit the closed loop gain that the amplifier is to be configured for. Thereby maximising the bandwidth. The higher the closed loop gain (lower the beta), the smaller can be the compensation capacitor giving a higher open loop gain and an increased bandwidth.
