A capacitor stores electricity as a static electric field. This is the same thing that happens when you walk across a carpet in socks and build up an electric charge, only to discharge it when you touch a door handle. You were acting as a capacitor! Inside a typical capacitor, you'll find two conductors separated by an insulating material.

A capacitor is an electrical component that stores energy in an electric field. It is a passive device that consists of two conductors separated by an insulating material known as a dielectric. When a voltage is applied across the conductors, an electric field develops across the dielectric, causing positive and negative charges to accumulate on the conductors.
