When a capacitor is faced with a decreasing voltage, it acts as a source: supplying current as it releases stored energy (current going out the positive side and in the negative side, like a battery). The ability of a capacitor to store energy in the form of an electric field (and consequently to oppose changes in voltage) is called capacitance.

Capacitors can act as filters on electric signals (as in the RC circuit) to create large pulses of currents and many more applications. The capacitance is the physical property used by capacitors to store charge. Geometric factors and fabrication details uniquely determine the capacitance of a device. We measure the capacitance in farads.

Capacitance is determined by the geometry of the capacitor and the materials that it is made from. For a parallel-plate capacitor with nothing between its plates, the capacitance is given by C 0 = e 0 A d, C 0 = e 0 A

The Class 1 capacitor is stable when compared to Class 2 capacitors type. Their capacitance will increase by increasing the temperature.so this gives a positive temperature coefficient. Capacitor Unit. The unit of capacitance is measured in terms of a farad, mostly in microfarads. Capacitance determines how much amount of charge it can store.
