A capacitor is an electrical component that stores energy in an electric field. It is a passive device that consists of two conductors separated by an insulating material known as a dielectric. When a voltage is applied across the conductors, an electric field develops across the dielectric, causing positive and negative charges to accumulate on the conductors.

To determine the amount of current that flows through the MOSFET when ON it is necessary to refer to the specifications and electrical characteristics for each element. Table 1 lists the relevant electrical characteristics. In the case of $V_{DS} = 10\text{V}$ a threshold voltage of between 1.0V and 2.5V is required for an I_D of 1mA.

An electrolytic capacitor is a polarized capacitor whose anode is a positive plate where an Al_2O_3 oxide layer is formed through electrochemical principles that limit the use of reverse voltage.

Aluminum electrolytic capacitors are polar capacitors and come with two lids of different lengths. On the other hand, non-polar capacitors (N-P-C) can be connected either way in a circuit design. Ceramic capacitors, film capacitors, and electrolyte capacitors are non-polar. P-C offers a large capacitance value in a tiny package.
