Capacitors can be used to filter out low frequencies. For example, a capacitor in series with a sound reproduction system rids it of the 60 Hz hum. Although a capacitor is basically an open circuit, there is an rms current in a circuit with an AC voltage applied to a capacitor. This is because the voltage is continually reversing, charging and ...

Therefore 0.00023 F multiplied by 9V = 0.00207 coulombs. And, with the three capacitors, we have 330uF (0.00033 F) multiplied by 9V = 0.00297 coulombs. We can also calculate the charge of each capacitor individually. We just use the same formula for each capacitor, you can see the answers on screen for that.

The same basic formula holds true, because time is irrelevant to voltage, current, and resistance in a component like a resistor. In a capacitor, however, time is an essential variable, because the current is related to how rapidly voltage changes over time. To fully understand this, a few illustrations may be necessary.

Capacitance is the measure of the electric charge that can be held by a conductor is defined as the ratio of the charge of the capacitor to the potential of the capacitor. The capacitance formula is expressed as C = Q / V. When the capacitors are connected in series, the capacitance formula is expressed by C = 1/C + 1/C = 2. Again, the capacitance formula is expressed by C = C + 1 + 1/C = 0.
