This letter represents the tolerance of the capacitor, meaning how close the actual value of the capacitor can be expected to be to the indicated value of the capacitor. If precision is important in your circuit, translate this code as follows: B = ± 0.1 pF. C = ± 0.25 pF. ...

As the capacitor is being charged, the charge gradually builds up on its plates, and after some time, it reaches the value Q . To move an infinitesimal charge dq from the negative plate to the positive plate (from a lower to a higher potential), the amount of work dW that must be done on dq is ($dW = W$, $dq = \frac{q}{C}$).

capacitors as shown in Figure 2 (a). The impedance of an ideal capacitor is only the reactance $Z = X = 1/\omega C = 1/2\pi fC$. For example, a 100 nF ideal capacitor at 50 Hz will have about $Z_{ideal@50Hz} = X_{@50Hz} = 31.831 \Omega$. We can call this a capacitive dropper circuit. The reactance of the capacitor is taking the
