A resistor is a fundamental passive component in electronic circuits, primarily used to provide resistance to the flow of electrical current, hence its name "resistor." As a passive component, it does not actively supply energy to the circuit; instead, it converts electrical energy into heat and dissipates it.

In a cardiac emergency, a portable electronic device known as an automated external defibrillator (AED) can be a lifesaver. A defibrillator (Figure (PageIndex{2})) delivers a large charge in a short burst, or a shock, to a person's heart to correct abnormal heart rhythm (an arrhythmia). A heart attack can arise from the onset of fast, irregular beating of the ...

Even better, because the switch cannot throw infinitely fast, there will be finite lengths of time during which one contact is arbitrarily close to the other, so the voltage gradient arbitrarily high. Hence, the spark will begin the very moment that they separate, and will simply be stretched out as they are pulled further apart. Moreover, this ...

In a resistor, that kinetic energy is converted to thermal energy or heat. Why does voltage drop across a resistor? A couple key points: The potential energy of an electron going into a resistor is higher than the potential energy of an electron going out of a resistor. Potential energy from charges or kinetic energy from moving electrons is ...

The function of a resistor is to oppose the electric current through it. This is called electrical resistance, and is measured in the unit ohm (represented by the Greek uppercase letter omega, Ω). The resistance can be calculated with Ohm's law, when the voltage drop across the resistor and the current through the resistor are known:

function of the geometric characteristics of the capacitor - plate separation (d) and plate area (A) - and by the permittivity (ϵ) of the dielectric material between the plates. $C = \frac{\epsilon A}{d}$ (1.4) Capacitance represents the efficiency of charge storage and it is measured in units of Farads (F). The current-voltage relationship of a capacitor is ...

The electric fields surrounding each capacitor will be half the intensity, and therefore store one quarter the energy. Two capacitors, each storing one quarter the energy, give half the total energy storage. Since capacitance is inversely related to energy storage, this implies that identical capacitances in parallel give

double the capacitance.

This expression for V can be interpreted as the voltage drop across a resistor produced by the flow of current I . The phrase IR drop is often used for this voltage. For instance, the headlight in Example 20.4 has an IR drop of 12.0 V. If voltage is measured at various points in a circuit, it will be seen to increase at the voltage source and decrease at the ...
