When you press the button the capacitor charges through the LED, and quickly, because you don"t have a series resistor to limit the current. Once the capacitor voltage is a couple of volts (the LED voltage) below Vcc charging stops and the LED goes out. Add a series resistor to slow down the charging of the capacitor. The current will be ...

A resistor-capacitor, or RC, circuit is an important circuit in electrical engineering; it is used in a variety of applications such as self-oscillating, timing, and filter circuits, these are just to name a few examples this lab, you will investigate how the RC circuit responds when a DC voltage source is applied to it and learn about the charging and discharging properties of the capacitor.

The purpose of this experiment is to investigate the physics of capacitors in circuits. The charging and discharging of a capacitor is the actual movement of electrons into and out of ...

This circuit uses two 470uF electrolytic capacitors in parallel to increase the capacitance. By connecting multiple capacitors in parallel, we can get an equivalent capacitor with a larger capacity. This is done to extend the time the LED light stays on, making it easier to observe the charging and discharging process of the capacitors.

Usually capacitors of the size ...

A capacitor is a device used to store electrical charge and electrical energy. It consists of at least two electrical conductors separated by a distance. (Note that such electrical conductors are sometimes referred to as "electrodes," but more correctly, they are "capacitor plates.") The space between capacitors may simply be a vacuum, and, in that case, a capacitor is then known as ...
