EE 1202: Introduction to Electrical Engineering Experiment #4: Capacitor and Inductor Circuits 2 experimenter). The Farad is a very large measure of capacitance, so capacitors usually have values of micro-(10 6), and pico-(10 12)Farads. 3.2 ductor: An inductor is a coil of wire with the property of electrical inertia.

When we find the electric field between the plates of a parallel plate capacitor we assume that the electric field from both plates is $fE=\frac{\sin \{2epsilon_0\}}{1}$ The factor of two in the denominator comes from the fact that there is a surface charge density on both sides of the (very thin) plates.

The capacitor transducers are used for the measurement of linear and angular displacement. This uses the concept of change of capacitance by a change in overlapping area and distance between the capacitor plates. For the measurement of object displacement, one plate of the capacitance transducer is kept fixed, while the other plate is connected to the object.
