Surface Mount Multi-Layer Ceramic Capacitors (MLCC) primarily fail in the cracking regime. That is the ultimate failure mode of a capacitor is with a body crack. MLCC are made of very fine intermeshing metallic layers embedded in a ceramic substrate. A large portion of these failures result in short circuits (low

impedance path) through the part.

Cracking remains the major reason of failures in multilayer ceramic capacitors (MLCCs) used in space electronics. Due to a tight quality control of space-grade components, the probability that as manufactured capacitors have cracks is relatively low, and cracking is often occurs during assembly, handling and the following testing of the systems.

In ceramic capacitors, long storage times can result in a loss of capacitance. In aluminum capacitors, this induces more leakage current, due to the aluminum oxide layer slowly dissolving into the liquid electrolyte.

As this happens, the leakage current of the capacitor can be high, especially when it is first energized.
