Above, we calculated the power. So now we use the above formula to calculate the current (amps) that the inverter will take from the battery. Power = Amps x Volts 110 watts = amps x 12 Therefore amps (every second, every hour, same thing; it's continuous) = $110/12 = 9.16$ amps. So at any moment, the inverter will need to draw 9.16 ...

The voltage level of the battery determines the maximum electrical power which can be delivered continuously. Power P [W] is the product between voltage U [V] and current I [A]: $[P = U \cdot I]$ The higher the current, the bigger the diameter of the high voltage wires and the higher the thermal losses.

This gives the power in terms of only the current and the resistance. Thus, by combining Ohm's law with the equation $P = I^2 R$ for electric power, we obtain two more expressions for power: one in terms of voltage and resistance and one in terms of current and resistance. Note that only resistance (not capacitance or anything else), current, and ...
