The applications of the variable capacitor include the following. Trimmer capacitors are used where a capacitance value is needed to be matched to a particular circuit in the manufacturing process. The main reason to use this capacitor is, the components used in the circuit have own tolerances. So the tolerance values can be changed by 20%

0 parallel plate $Q = \frac{C}{V} = \frac{Q}{V} = \frac{Q}{d} = \frac{Q}{\epsilon_0 \epsilon_r \frac{A}{d}} = \frac{Q d}{\epsilon_0 \epsilon_r A}$ (5.2.4) Note that C depends only on the geometric factors A and d . The capacitance C increases linearly with the area A since for a given potential difference V , a bigger plate can hold more charge. On the other hand, C is inversely proportional to d , the distance of separation because the smaller the value of d , the smaller the potential difference ...

Although the values of the capacitors are the same (eg. 35 volts 2200 μ f) some capacitors come out more robust and longer life. How can I measure the difference in quality? I can measure the capacitance with a multimeter, and I can measure the ESR with an LCR meter. How else do you check? For example, I cannot test the operating voltage.

1.) Losses in a capacitor characterized by the quality factor of a capacitor is a measure of the imaginary to real part of the impedance or admittance $Q = 1 / CR_s = CR_p$ where R_p is the equivalent resistance in parallel with the capacitor, C , and R_s is the electrical series resistance (ESR) of the capacitor, C . 2.)
