Charging a lithium battery below -0°°C (32°°F) can cause lithium plating on the battery's anode, leading to permanent capacity loss and increased risk of internal short circuits and safety hazards. It's advised to charge lithium batteries at temperatures above freezing and, ideally, close to room temperature.

Without it, the storage of energy in EVs would not be possible. A lithium-ion battery cell contains two types of electrodes: anode and cathode. Due to their remarkable ability in storing lithium ions (energy), anodes and cathodes are the primary reason why lithium-ion batteries are used in EVs.

Simply put, the battery is very sensitive to temperature, the lower the ambient temperature, the worse the battery's charge-discharge capability, battery capacity, and transmission impedance.
