Since charge builds up on a capacitor rather than flowing through it, charge can build up until the point that the potential difference  $DV=Q / C$  balances out the external voltage (electromotive force of the source) pushing charge onto the capacitor. capacitance. If the time variation of the signal is fast enough the capacitor cannot fully charge and discharge completely. Let's see how this affects a square wave. The square wave is a difficult signal to produce because it requires abrupt changes in voltage.

Figure 1 As the current flows, the charge  $q$  is depleted, reducing the potential across the capacitor, which in turn reduces the current. This process creates an exponentially decreasing current, modeled by  $V(t) = V_0 e^{-t/RC}$ . The rate of the decrease is determined by the product  $RC$ , known as the time constant of the circuit. A large time ...
