With the increasing market demand for high-performance lithium-ion batteries with high-capacity electrode materials, reducing the irreversible capacity loss in the initial cycle and compensating for the active lithium loss during the cycling process are critical challenges. Pre-lithiation addresses this issue by adding extra lithium to the anode during the battery manufacturing process, essentially compensating for the lithium ions that are lost during the first cycle. This not only improves the initial efficiency of the battery but also enhances its overall energy density, making it more powerful and efficient over time.
