That's the mechanical analogy for pure reactive power system - in this case a LC circuit, where energy is exchanged between an inductor and a capacitor. In a single-phase power system, reactive power comes from the interaction of generator windings and any inductive loads on the system, and it's bad because then you have this energy exchange ...

In a DC circuit, the product of "volts x amps" gives the power consumed in watts by the circuit. However, while this formula is also true for purely resistive AC circuits, the situation is slightly more complex in an AC circuits containing reactive components as this volt-amp product can change with frequency affecting the circuits reactive power.
