The band gap energy (Eg) of a semiconductor is the minimum energy required to move an electron from the valence band to the conduction band, thus making it a critical parameter that governs the electrical and optical properties of semiconductors. As temperature increases, the band gap energy of a semiconductor typically decreases.

The Si-C double layers are taken into consideration in this type of representation. The polytype is distinguished, together with Bravais lattice of the crystal giving the order of periodicity "n". Since 1991, the SiC semiconductor has gained much importance to128].

Energy density corresponds to the energy accumulated in a unit volume or mass, taking into account dimensions of electrochemical energy storage system and its ability to store large amount of energy. On the other hand power density indicates how an electrochemical energy storage system is suitable for fast charging and discharging processes.

Electrical resistance (R) is the resistance to a flow of electric current through a material. The electrical resistance of a material is proportional to its length (l) and inversely proportional to its cross-sectional area (A). Each material has also an intrinsic property called electrical resistivity (r). Electrical resistance (R) is expressed as follows as a function of r, I and A.
