Today, graphite is by far the most used material for the negative electrode material in lithium-ion batteries (LIBs). At first sight, the use of graphite in sodium-ion batteries (SIBs) would be only logical.

It is well-known that for alloy- or conversion-type electrode materials, volume expansion and shrink during reactions result in strain and fracture of electrode material particles. Compared with these materials, the much smaller volume change of graphite during Li ion intercalation contributes to its much better cycle stability.
