As a battery ages, it loses water, leaving the top of the lead plates exposed to the air inside the battery case. Over time, this can lead to warpage of the plates. When the driver starts the engine, the heavy demand for power can cause these already warped plates to flex, touch and thus spark, says Steve Mazor, head of engineering and safety for the Automobile Club of Southern California.

How do alkaline batteries compare to LiFePO<sub>4</sub> batteries in terms of temperature tolerance? LiFePO<sub>4</sub> batteries generally exhibit superior temperature tolerance compared to alkaline batteries. They can operate effectively from -10°C to 60°C (14°F to 140°F) without significant performance loss, while alkaline batteries are best kept within a narrower range.

On the other hand, when the temperature rises, so does the size of the battery. However, while high temperatures improve a battery's capacity, they have the reverse effect of shortening its battery life. When the temperature rises to 22 F, ...

Do not expose batteries to extreme temperatures (either hot or cold), which can damage the battery and cause it to malfunction. Store batteries in a cool, dry place away from flammable materials. Do not puncture or damage batteries, which can cause a short circuit and lead to an explosion or fire.

High temperatures can cause the capacity of a battery to decrease, while low temperatures can cause the state of charge to decrease. It is important to note that the effect of temperature on battery life depends on the type of battery. For example, lithium-ion batteries have a higher energy density and nominal capacity than lead-acid batteries.

A commonly used household product, likely in your home right now, can have dangerous consequences if not used properly, a fact highlighted by scenes of explosions, fires and injuries nationwide.
