

A single solar cell (roughly the size of a compact disc) can generate about 3-4.5 watts; a typical solar module made from an array of about 40 cells (5 rows of 8 cells) could make about 100-300 watts; several solar panels, each made from about 3-4 modules, could therefore generate an absolute maximum of several kilowatts (probably just ...

Polyvinylpyrrolidone (PVP) has been successfully used as the cathode interfacial layer (CIL) in organic solar cells (OSCs) for work function (W F) modification. However, detailed insight into the effect of a PVP interlayer on the physicochemical properties of the indium tin oxide (ITO) electrode in inverted OSCs (I-OSCs) is still largely absent.

A solar cell is made of two types of semiconductors, called p-type and n-type silicon. The p-type silicon is produced by adding atoms--such as boron or gallium--that have one less electron in their outer energy level than does silicon. Because boron has one less electron than is required to form the bonds with the surrounding silicon atoms, an electron vacancy or "hole" is created.

Here, the difference of work functions is absorbed in thin interfacial layers, such as the transparent conduction oxide/TiO 2 interface in the particular case of sensitized solar cells. In fact, Si solar cells have a similar selectivity mechanism where the band bending produced by the p-n junction is limited to a very narrow interfacial layer ...

The light absorption mechanism is key to how solar cells work. When sunlight hits a solar cell, it starts various photon-electron interactions important for making energy. These interactions happen when photons, or light particles, hit electrons in the cell. This gives electrons the push they need to break free from atoms. Once free, these ...

The work function of the back contact has a significant role in the HTL-free PSC performance. A back contact work function of 5.40 eV or more can eliminate the need for an HTL in MAPbI 3 perovskite-based solar cells due to the suitable barrier height for electrons that form at MAPbI 3 /back contact interface.

Each component layer of the perovskite solar cell, including their energy level, cathode and anode work function, defect density, doping density, etc., affects the device's optoelectronic properties. For the numerical modelling of perovskite solar cells, we used SETFOS-Fluxim, a commercially available piece of software.
