The working principle of transformer is based on mutual induction between two coupled coils. According to this principle a changing flux creates an induced e.m.f in each turn equal to the derivative of the flux so that the total induced e.m.f across N turns is, $[E=\frac{N\phi}{dt}]$ This can be seen in transformer shown in figure 1.

Working Principle. This sensor is usually mounted on the throttle body. It senses the position of the throttle valve or butterfly valve and transmits the information to the Engine control unit. This sensor monitors how far down the accelerometer pedal is pushed and gives the output current determining the position of the pedal.

A solenoid valve works by having a plunger move up and down based on the magnetic field generated from the electrical solenoid. The plunger either opens or closes the orifice that the media flows through.

When the valve is opened, the core uncovers the orifice, relieving the pressure on top of the diaphragm. The line pressure then forces the valve open. Externally Piloted. This type of valve operates on a similar principle to internally piloted valves, but it uses fluid from an external source to actuate the valve.

The transformer is based on two principles: first, that an electric current can produce a magnetic field (electromagnetism), and, second that a changing magnetic field within a coil of wire induces a voltage across the ends of the coil (electromagnetic induction). Changing the current in the primary coil changes the magnetic flux that is developed.
